

Text to Cols JMP Add-In, Version 3

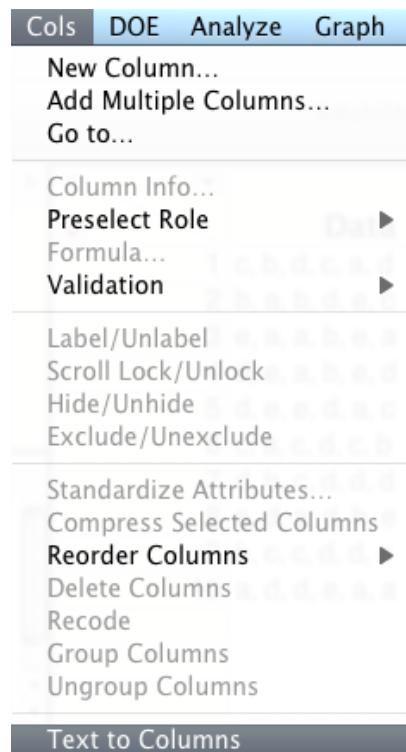

Written by Jeff Perkinson

The diagram illustrates the transformation process. On the left, a screenshot of a JMP data table shows a single column labeled "Data" containing 10 rows of comma-delimited text. Two large white arrows point from this table to the right, indicating the transformation. On the right, a second screenshot shows the same 10 rows, but each row now has six new columns to its right, labeled "Data 1" through "Data 6". These new columns contain the individual characters from the original "Data" column, separated by commas.

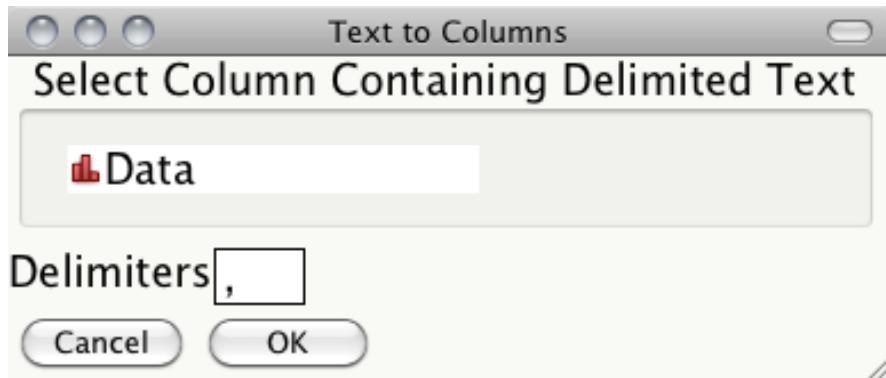

| | Data 1 | Data 2 | Data 3 | Data 4 | Data 5 | Data 6 |
|----|--------|--------|--------|--------|--------|--------|
| 1 | c | b | d | c | a | d |
| 2 | b | a | b | d | e | c |
| 3 | e | a | a | b | e | a |
| 4 | d | e | a | b | e | d |
| 5 | d | e | e | d | a | c |
| 6 | c | a | c | d | c | b |
| 7 | d | b | c | d | d | d |
| 8 | e | d | a | d | b | e |
| 9 | b | c | c | d | d | c |
| 10 | a | d | d | e | a | a |

Text to Cols creates new columns from a column of delimited text. As shown above, the column “Data” has a comma-delimited string. Text to Cols creates the six new columns to the right.

After installing the Text to Cols add-in, you’ll find a new menu at the bottom of the Cols menu.

When you select this menu item, you'll be prompted to choose a column of text and specify the delimiter.

Select your column and click OK.

New columns are added to the data table to contain the values from your column. Each new column has a formula using the Word() function to derive its value.

Calling Text To Cols from JSL

Version 3 adds support for calling Text To Cols from JSL by adding a com.jmp.jperk namespace with a function.

```
com.jmp.jperk:texttocols( column, delimiters, <data  
table=current data table()>)
```

Description

Creates new columns in data table from a column of text using delimiters to define each column

Returns

An associative array

```
{ {"columns", list of columns created}, {"name",  
text string with name of column group containing  
columns} }
```

Arguments

column a JSL column reference of a text column to be split into multiple columns

delimiters a string of characters to be used as delimiters

data table optional reference to a data data table that column is in and to which should the new columns will be added. Current Data Table() will be used if no data table is specified.

Example:

```
bc_party = Open( "$SAMPLE_DATA\Consumer  
Preferences.jmp" );  
  
com.jmp.jperk:texttocols( Column( bc_party ,  
"floss delimited"), ",", bc_party );
```

Support
