	5.39	0.32	7.65		

SINGULAR VALUE DECOMPOSITION

 Singular vectors (U, V) are orthogonal to each other and have unit length (orthonormal).

• Singular values, **S**, can be used to stretch out the vectors in **U** and **V** so they're no longer normalized but reflect the importance of each dimension.

SINGULAR VALUE DECOMPOSITION

- Redundancies in the original data are also reflected in the basic structure matrices.
 - The maximum number of meaningful dimensions in X is the rank of X
 - Nonzero elements in S
- If **X** is symmetric, the singular vectors **U** and **V** will be identical.
 - Because pre- or post-multiplying a matrix by its transpose makes it symmetric, the basic structure matrices of X, X^TX, and XX^T, reveal the same basic structure.
 - Eigenvalue decomposition can also reveal the basic structure of X

 $\begin{aligned} X^T X &= V S U^T U S V^T = V S^2 V^T \\ X X^T &= U S V^T V S U^T = U S^2 U^T \end{aligned}$

WHY THE LONG INTRO?

- All multivariate techniques in this session are based on:
 - Decompositions of transformed matrices:
 - Center, normalize, proportion, double-center, etc.*
 - Dimension reduction
- The techniques only differ in:
 - Pre-decomposition transformations of **X**
 - Post-decomposition transformations of **U** and **V**
- * Note: transformations are sometimes implied (e.g., correlation matrices)

PRINCIPAL COMPONENTS ANALYSIS

- Used with continuous data
- Goals of Analysis:
 - Identify underlying structure of data
 - Study inter-association of variables
 - Reduce dimensionality of data
 - Simplify ensuing analyses
 - Study inter-individual variability
 - Extract dimensions that distinguish individuals
 - Identify multivariate outliers
 - Measure latent variables (but Factor Analysis can be better for this)

PRINCIPAL COMPONENTS ANALYSIS

- Most often known as the result of eigenvalue decomposition on a correlation (or covariance) matrix
- Key output:
 - Eigenvalues (aka squared singular values)
 - Eigenvectors
 - Loadings
 - Percent of variance explained by each dimension
 - Principal component scores

PRINCIPAL COMPONENTS ANALYSIS

Unit length eigenvectors indicating main directions in data

Magnitude of each dimension from most to least important

Rescaled eigenvectors

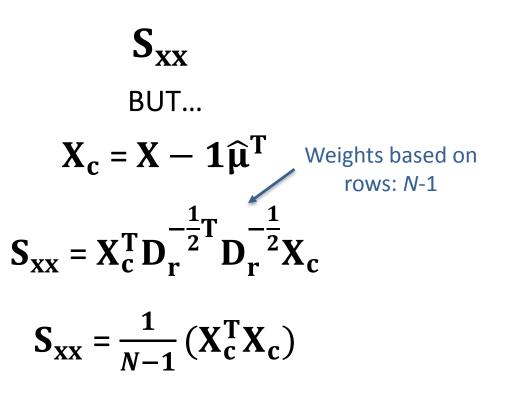

3-D Cloud for illustration

Eigenvalue decomposition of the covariance matrix of X:

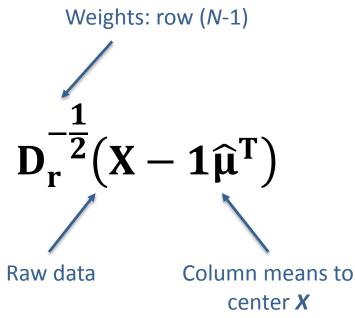

- Center X
- Sum of squares of centered X
- Divide all entries by *N*-1

PRINCIPAL COMPONENTS ANALYSIS

Alternatively, SVD of:

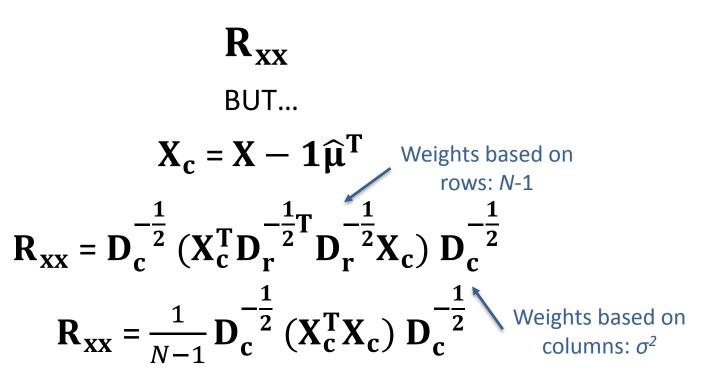

- Center X
- Multiply each row by $\frac{1}{\sqrt{N-1}}$
- Multiply each column by the inverse of its corresponding standard deviation

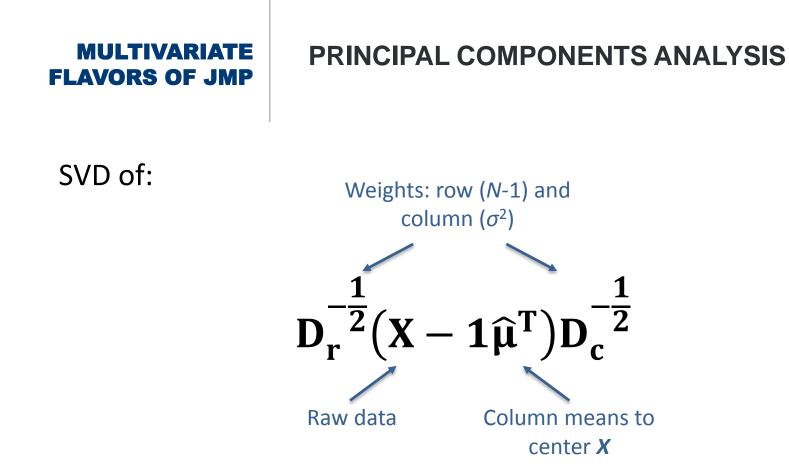

Eigenvalue decomposition of the correlation matrix of X:

- Center X
- Sum of squares of centered X
- Multiply each row and column by the inverse of the corresponding standard deviation
- Divide all entries by N-1

- Center X
- Multiply each row by $\frac{1}{\sqrt{N-1}}$
- Multiply each column by the inverse of its corresponding standard deviation

PRINCIPAL COMPONENTS ANALYSIS

SVD of:

$\boldsymbol{D}_r^{-\frac{1}{2}} \big(\boldsymbol{X} - \boldsymbol{1} \widehat{\boldsymbol{\mu}}^T \big) \boldsymbol{D}_c^{-\frac{1}{2}} = \boldsymbol{U} \boldsymbol{S} \boldsymbol{V}^T$

	*							Þ	

- **Component Scores** characterize the degree of endorsement of each dimension for every observation
- PCA Scores can be used in a variety of subsequent analyses (e.g., predictive models)
- Score plot facilitates identification of observations with very high/low scores and those close to the centroid

T² Contribution Plots for Selected Samples

PSHerbal

psspicy

PSCIIIUS

Variable

Sample=26

2

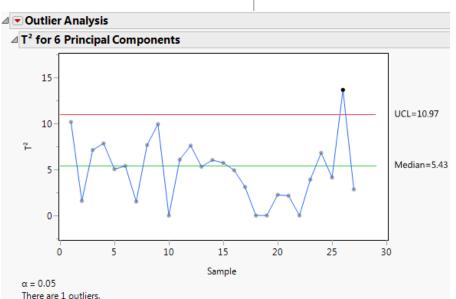

1

-2

-3 -

Contribution

PRINCIPAL COMPONENTS ANALYSIS

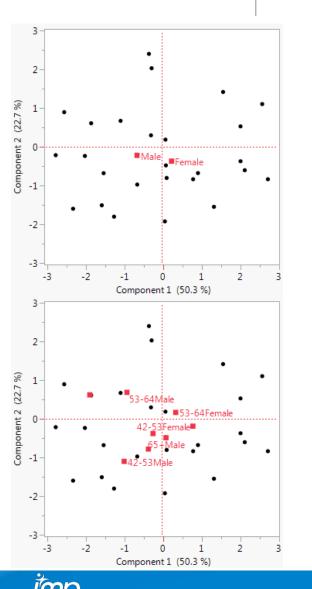

- New to JMP 14: **Outlier Analysis**
- Enables identification of out-of-control points (multivariate outliers) through the T² statistic

• **Contribution plots** indicate exactly which variables are contributing most to the extreme observations

PRINCIPAL COMPONENTS ANALYSIS

- **Supplementary variables** can be included to enrich interpretation of components
- Supplementary points are displayed at the averages of the scores of the corresponding respondents
 - E.g., Average of component scores for males and females results in coordinates for points in each dimension/component
- Creating "interaction" variables enables more nuanced interpretation of the plots

MULTIPLE CORRESPONDENCE ANALYSIS

- Used with categorical data (ordinal or nominal)
- Goals of Analysis:
 - Goals are similar to PCA but there is much more emphasis on graphical displays
 - Identify underlying structure of data
 - Study inter-association of variable *categories*
 - Study inter-individual variability
 - Extract dimensions that distinguish individuals
 - Identify multivariate outliers

MULTIPLE CORRESPONDENCE ANALYSIS

- Key output:
 - MCA Map
 - Principal inertias (eigenvalues): adjusted values
 - Principal coordinates (loadings)
 - Dimension contributions to column inertia (variance overlap between point and dimension)
 - Column contributions to total inertia
 - Column contributions to individual dimensions
 - Dimension contributions to total inertia (explained variance of each dimension)

MULTIPLE CORRESPONDENCE ANALYSIS

• Known as the decomposition of an Indicator matrix or a Burt matrix

Indicator	VS	Burt
Ζ		$\mathbf{C} = \mathbf{Z}^{T}\mathbf{Z}$

- The choice makes a difference in the overall "inertia" (eigenvalues, variance) of the solution, but not on the substantive interpretations
 - Use adjusted inertia

- Determine ideal number of dimensions:
 - Pareto plot: Use as scree plot. Number of eigenvalues before the elbow
 - Dimensions that sum up to ~80% of adjusted percent of inertia
 - All dimensions with coherent substantive meaning
- Adjusted inertias give a more accurate idea of the percentage of explained variance

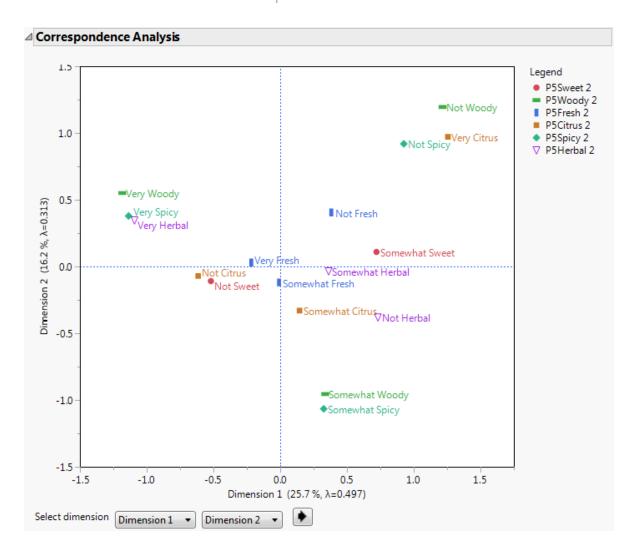

•

- Benzécri adjusted inertias are computed as percentages of the sum of eigenvalues that are greater or equal to 1/number of column variables
 - Inertias tend to be overestimated
- Greenacre adjusted inertias are less optimistic than Benzécri's

MULTIPLE CORRESPONDENCE ANALYSIS

- MCA Map is the key feature and contains huge amounts of information
- Points are plotted according to the column coordinates
- Project points onto each dimension to help interpret dimension's meaning
- Points close to each other are more strongly associated

P5Spicy 2	Not Spicy	0.925	0.920	-0.178
P5Spicy 2	Somewhat Spicy	0.325	-1.065	0.376
P5Spicy 2	Very Spicy	-1.136	0.379	-0.228
P5Herbal 2	Not Herbal	0.731	-0.379	1.291
P5Herbal 2	Somewhat Herbal	0.362	-0.034	-0.740
P5Herbal 2	Very Herbal	-1.092	0.347	0.179

- Column (principal) Coordinates are like PCA loadings. They help us interpret meaning of components
- Column Coordinates are particularly helpful when MCA map is too crowded: we can sort them to identify which categories are at the extremes

🖉 💌 Graph Builder

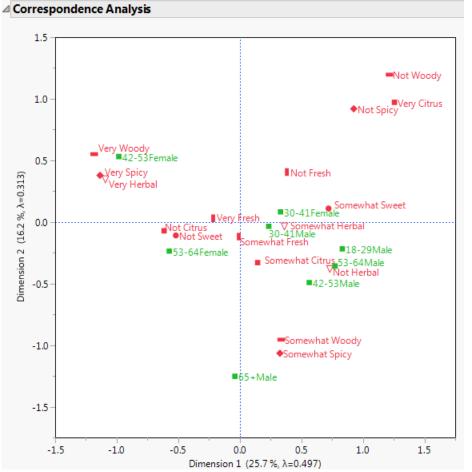

- Save Coordinate Formula saves Principal Row Coordinates to the data table, which characterize the degree of endorsement of each dimension for every observation
- As with PCA Scores, these can be used in a variety of subsequent analyses (e.g., predictive models)
- We can plot row coordinates to identify observations with very high/low scores and those close to the centroid

MULTIPLE CORRESPONDENCE ANALYSIS

- As with PCA, **Supplementary variables** can be included to enrich interpretation of dimensions
- Supplementary points are displayed at the averages of the principal row coordinates of the corresponding respondents
 - E.g., Average for males and females results in coordinates for points in each dimension
- Creating "interaction" variables enables more nuanced interpretation of the plots

- Used with continuous data
- Goals of Analysis:
 - Identify underlying structure of data from **multiple sources**
 - Study inter-association of variables across sources of data
 - Compare information from multiple data tables
 - Reduce dimensionality of data accounting for multiple-source structure (analogous to PCA on Corr vs Cov)
 - Study inter-association of observations (**products** in CR)
 - Extract dimensions that distinguish observations
 - Identify multivariate outliers within and across sources of data
- Graphical displays are also emphasized

- Determine ideal number of dimensions (most popular):
 - Scree plot: Number of eigenvalues
 before the elbow
 - Can use Pareto plot or plot eigenvalues in GraphBuilder
 - Number of eigenvalues larger than 1
 - Doesn't apply anymore in MFA
 - Dimensions that sum up to ~80% of variance
 - All dimensions with coherent substantive meaning

- Use Score Plot to identify how products "score" in each dimension
- E.g., Eucalyptus and Rosemary together with Tea Tree were rated as highly woody and spicy, whereas Sweet Orange and Lavender is correctly identified as high in sweet and citrus.
- Use Loading Plot to interpret meaning of consensus components
- Loadings are correlation coefficients between components/dimensions and variables

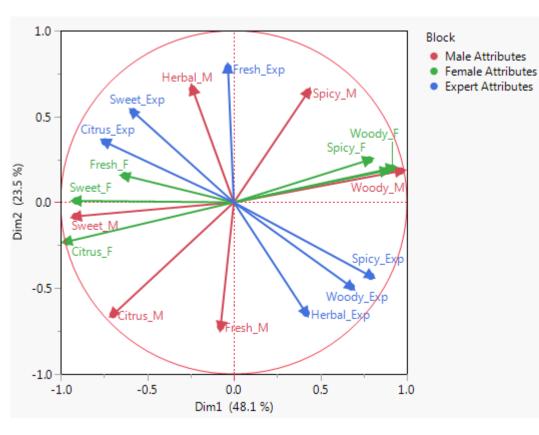

mn

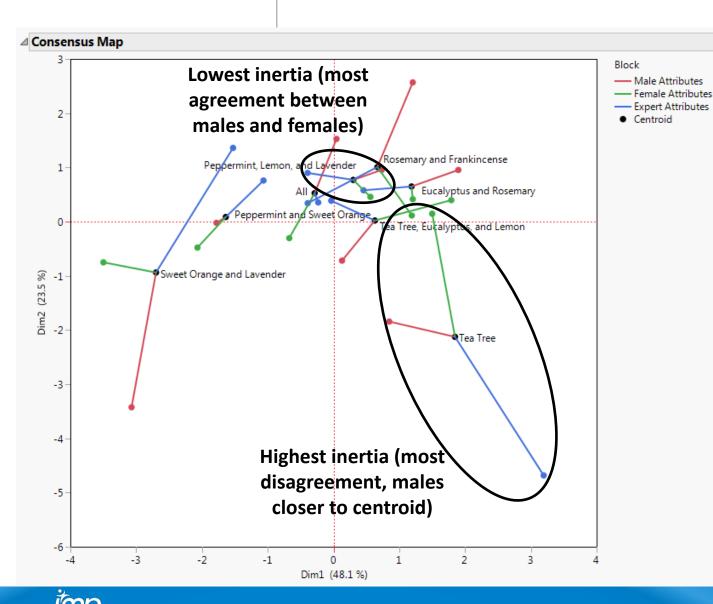

MULTIPLE FACTOR ANALYSIS

- Use Loading Plot to compare structure across sources
 - E.g., Males have higher dimensionality than females
- Vectors close to each other are more highly correlated
 - E.g., All sources mostly agree on perceptions of sweet and citrus
- Opposing vectors have opposite meaning
 - E.g., experts and males have opposite interpretation of freshness

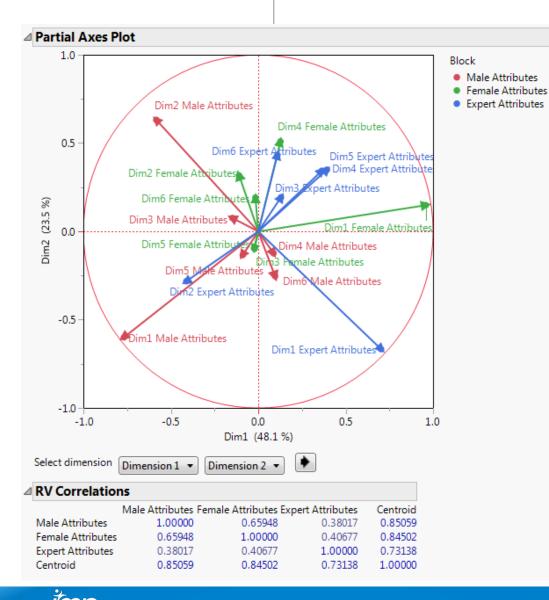

POWER TO KNOW

- Use Consensus Map to identify agreement or disagreement between sources.
 - "Highlight Product" slider facilitates this task by highlighting low/high inertia products
- Tea tree was experienced most differently across all
- Peppermint, lemon, and lavender was experienced most similarly across all
- Combination of "All" scents is closest to the origin

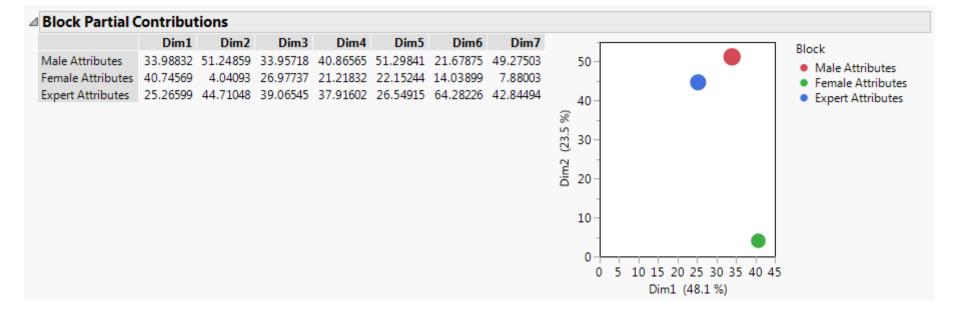

- Partial Axes Plot displays correlations between separate PCA dimensions across sources with MFA (consensus) dimensions
 - 1st MFA dimension is very much like females' 1st dimension from their own separate PCA
 - 2nd MFA dimension is most like males' own 2nd PCA dimension

- RV Correlations quantify the level of shared variance across sources (squared correlation coefficient between matrices)
 - Experts have the least in common with males and females

- Block Partial Contributions quantify the percentage of contribution to each MFA dimension from each block (i.e., source)
 - E.g., 1st MFA dimension is mostly influenced by females' responses and least by experts' responses

Males liked best the scents they perceived as citrus and somewhat sweet and fresh, and didn't like those scents they perceived as spicy.
