Surrogate Modeling of Stochastic Computer Simulation Data – Identifying Insurgents from a Helicopter Flying Surveillance

82nd MORS Symposium
Alexandria, VA
June 19th, 2014

Tom Donnelly, PhD
Systems Engineer & Co-insurrectionist

THE
POWER
TO KNOW.®

Outline

- Background and Goals
- Visualize Results
- Modeling Approaches
- Comparing Models
- Summary

Abstract

Data for identifying insurgents from a stochastic computer simulation of a helicopter flying surveillance for a convoy are modeled using several different methods. The six factors affecting Proportion Insurgents Identified (the response) are Helicopter Height, Helicopter Speed (relative to convoy), Helicopter Distance (from convoy), Convoy Speed, Number of Insurgents with AK47s, and Insurgent Camouflage level. Models employed include several types of decision tree, neural net, and regression (Generalized Linear Model). Relative strengths, weaknesses and prediction accuracy of models are compared. Discussion of the insights the different types of models offer is also presented.

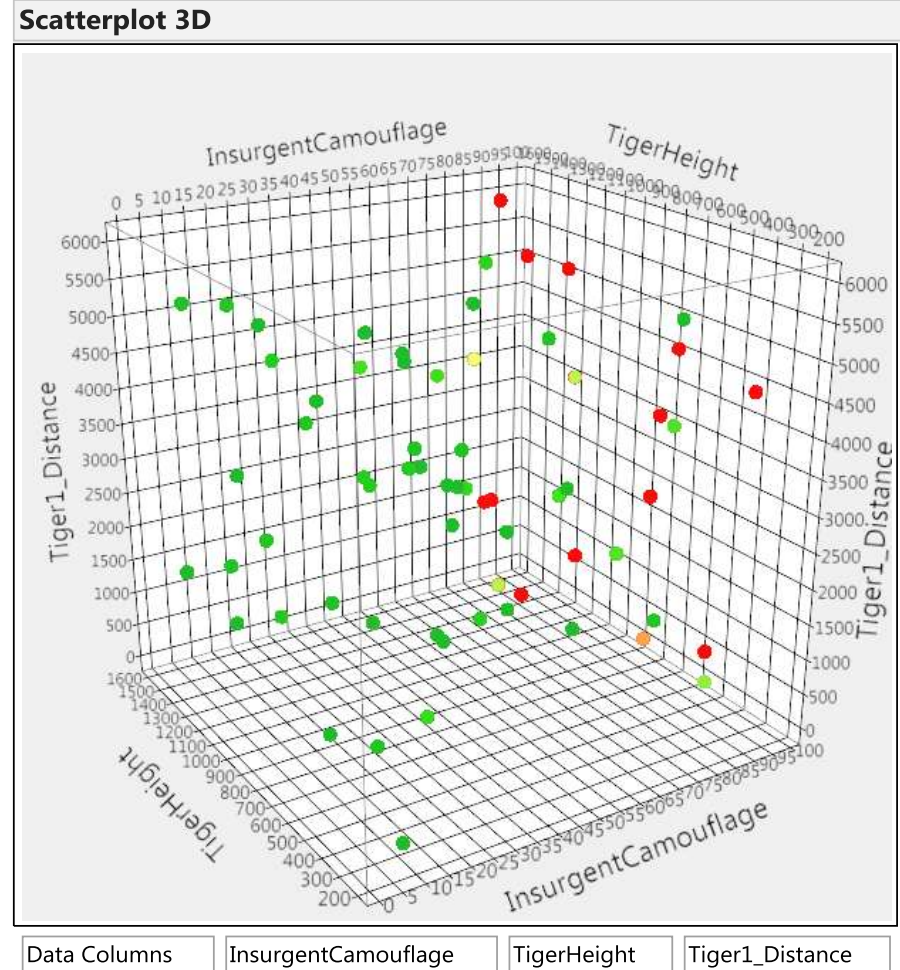

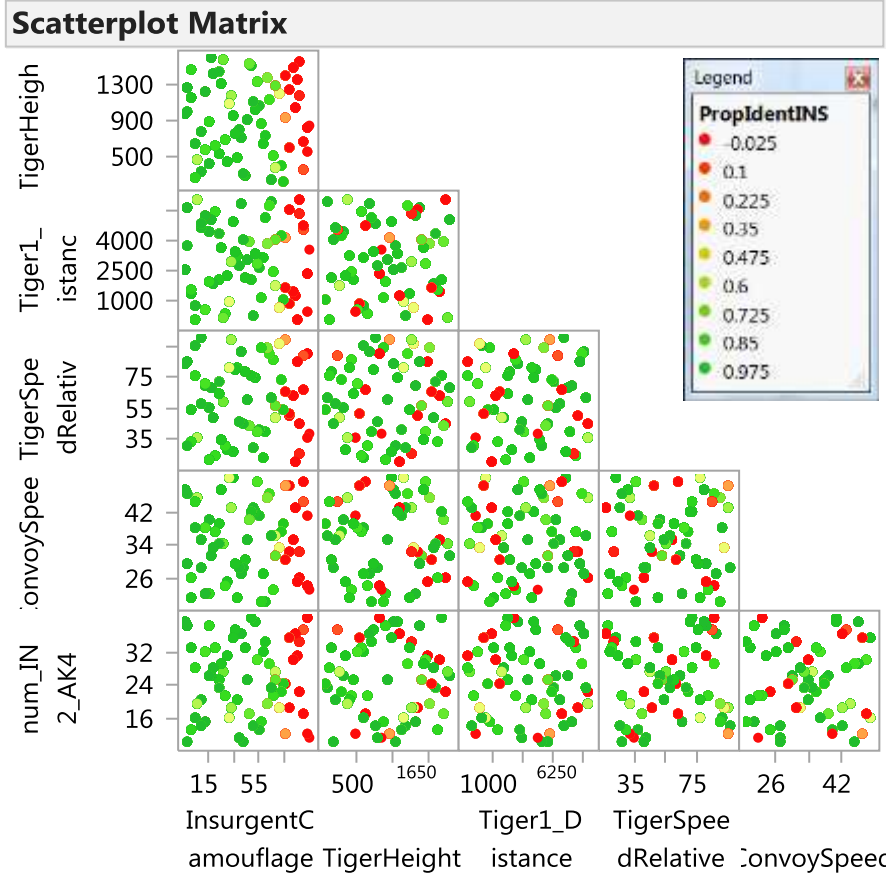

Surrogate Modeling of a Computer Simulation - Helicopter Surveillance – Identifying Insurgents

- 2009 International Data Farming Workshop - IDFW21, Lisbon, Portugal
- Largely German team (6 of 8) – their simulation
- 6500 simulations run overnight on cluster in Frankfurt
 - 65 unique combinations of 6 factors (each factor at 65 levels)
 - each case had 97 to 100 replications (lost a few)
- Response = Proportion of Insurgents Identified = *PropIdentINS* Data bounded between 0 and 1
- Explore data visually first
- Fit many different models – “Train, Validate (Tune), Test” 60/20/20 subsets
- Compare Actual vs. Predicted for Test Set

Goals

- Build a variety of surrogate models
- Evaluate and compare to choose best predictor
- Gain insight into simulation model
- Learn about different approaches to data mining

Preview End Result – Space-Filling DOE

Low detection associated with high levels of camouflage.

Why Use Design of Experiments Methods with Simulation Experiments?

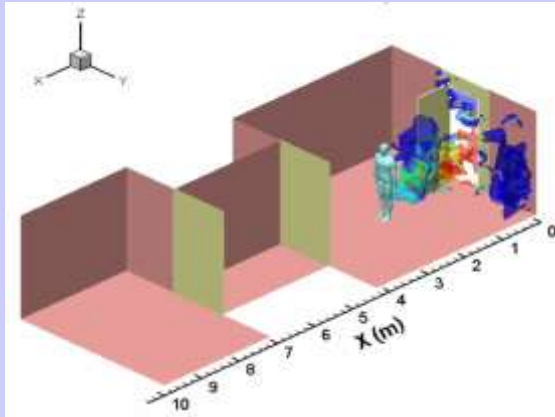

Quicker answers, lower costs, solve bigger problems

- Obtain a fast surrogate model of the simulation
 - Individual simulations can run for hours, days, weeks
 - » Computational Fluid Dynamics (CFD)
 - » Simulation runs in real-time
 - Numbers of factors can be very large (40+)
 - Numbers of simulations needed can be large (thousands in many cases)
 - Simulations can be stochastic requiring many replications
- Surrogate model yields a fast approximation of the simulation
 - more rapidly answer “what if?” questions
 - do sensitivity analysis of the control factors
 - optimize multiple responses and make trade-offs
- By running efficient subsets of all possible combinations, one can – for the same resources and constraints – *solve bigger problems*
- By running sequences of designs one can be as *cost effective as possible & run no more trials than are needed* to get a useful answer

Long Running Physics-Based Simulation

Detailed Physics Models can require a great deal of runtime to generate a short period of simulation time.

Before modeling look for correlations between good or poor levels of *PropIdentINS* and the factors.
 Strong correlation between poor *PropIdentINS* and high levels of *InsurgentCamouflage*.
 No other factor shows very much correlation with the response.

Prediction Profiler

Model Quotes

- “No *good* model ever accounted for all the facts, since some data was bound to be misleading, if not wrong.”
 - James Dewey Watson (1988)
- “Essentially, *all* models are wrong, but some are useful.”
 - George Box (1987)
- “The purpose of models is *not* to fit the data but to sharpen the questions.”
 - Samuel Karlin (1983)
- “The *best* material model of a cat is another, or preferably the *same*, cat.”
 - A. Rosenbleuth (1945)

What is a statistical model?

- An empirical model that relates a set of inputs (predictors, \mathbf{X}) to one or more outcomes (responses, \mathbf{Y})
- Separates the response variation into signal and noise

$$\mathbf{Y} = f(\mathbf{X}) + \mathbf{E}$$

- \mathbf{Y} is one or more continuous or categorical response outcomes
- \mathbf{X} is one or more continuous or categorical predictors
- $f(\mathbf{X})$ describes predictable variation in \mathbf{Y} (signal)
- \mathbf{E} describes non-predictable variation in \mathbf{Y} (noise)
- The mathematical form of $f(\mathbf{X})$ can be based on domain knowledge or mathematical convenience.

What is a predictive model?

- A type of statistical model where the focus is on predicting Y independent of the form used for $f(\mathbf{X})$.
 - There is less concern about the form of the model – parameter estimation isn't important. The focus is on how well it predicts.
 - Very flexible models are used to allow for a greater range of possibilities.
 - http://en.wikipedia.org/wiki/Predictive_modelling

What is a predictive model?

- Two Examples:

Regression

Nearest Neighbor

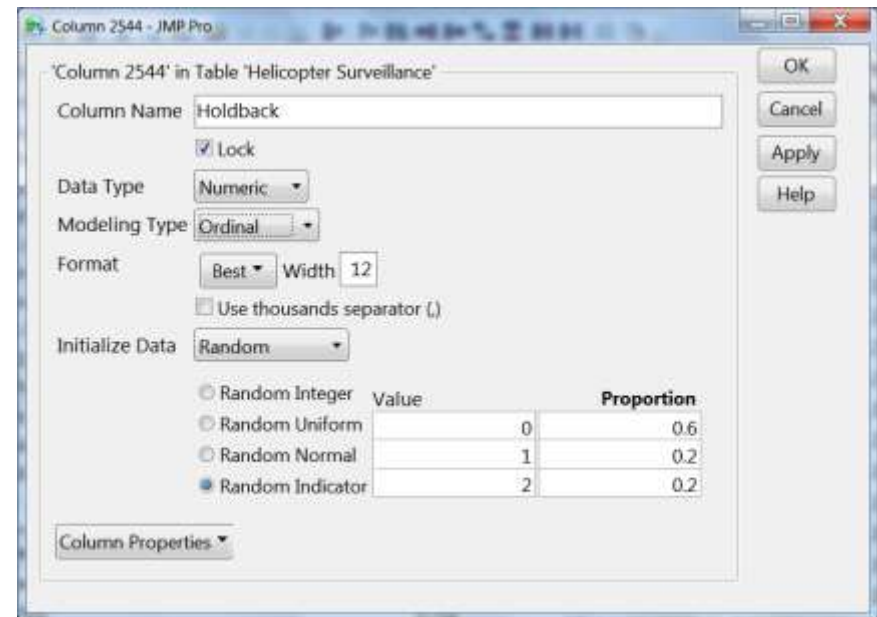

Preventing Model Overfitting

- If the model is flexible what guards against overfitting (i.e., producing predictions that are too optimistic)?
 - Put another way, how do we protect from trying to model the noise variability as part of $f(\mathbf{X})$?
- Solution – Hold back part of the data, using it to check against overfitting. Break the data into two or three sets:
 - The **training** set is used to **build** or **fit** the model
 - The **validation** set is used to **select** model by determining when the model is becoming too complex – it **tunes** the parameters
 - The **test** set is often used to **evaluate** how well model predicts independent of training and validation sets
 - Common methods include random holdback and k-fold crossvalidation

Honest Assessment Approach Using Train, Validate (Tune), and Test Subsets

Used in model selection and estimating its prediction error on new data

Decision Trees

- Also known as Recursive Partitioning, CHAID, CART
- Models are a series of nested IF() statements, where each condition in the IF() statement can be viewed as a separate branch in a tree.
- Branches are chosen so that the difference in the average response (or average response rate) between paired branches is maximized.
 - For all factors bin factor values or levels into two buckets such that the means of the two buckets are as far apart as possible.
 - Split on factor with the biggest difference in bucket means.
- Tree models are “grown” by adding more branches to the tree so the more of the variability in the response is explained by the model

Decision Tree Step-by-Step

Goal is to predict “Rejects” & “Accepts”

Overall Accept Rate is 84.44%

Overall Reject Rate is 15.56%

| Atom. Pressure | 3.36570749 | 0.149475063 | 58.787 | |

Candidate “X’s”

- Search through each of these
- Examine Splits for each unique level in each X
- Find Split that maximizes “LogWorth”
 - Will find split that maximizes difference in proportions of the target variable

Decision Tree Step-by-Step

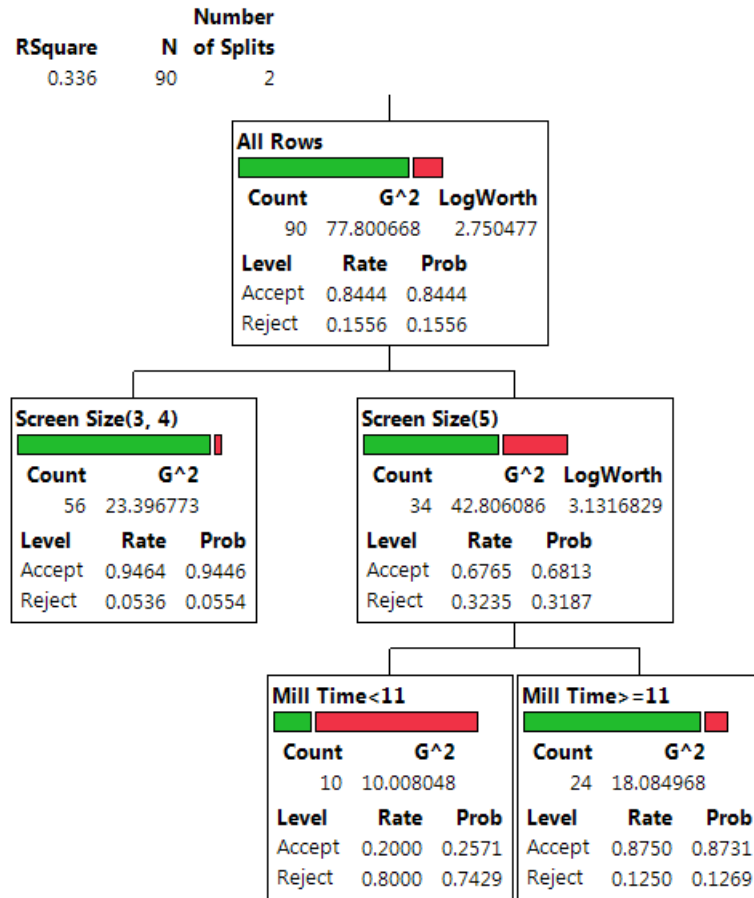

1st Split:

Optimal Split Screen Size 3 & 4 vs. Screen Size 5

Notice the difference in the rates in each branch of the tree

Repeat "Split Search" across both "Partitions" of the data. Find optimal split across both branches.

Decision Tree (Step by Step)

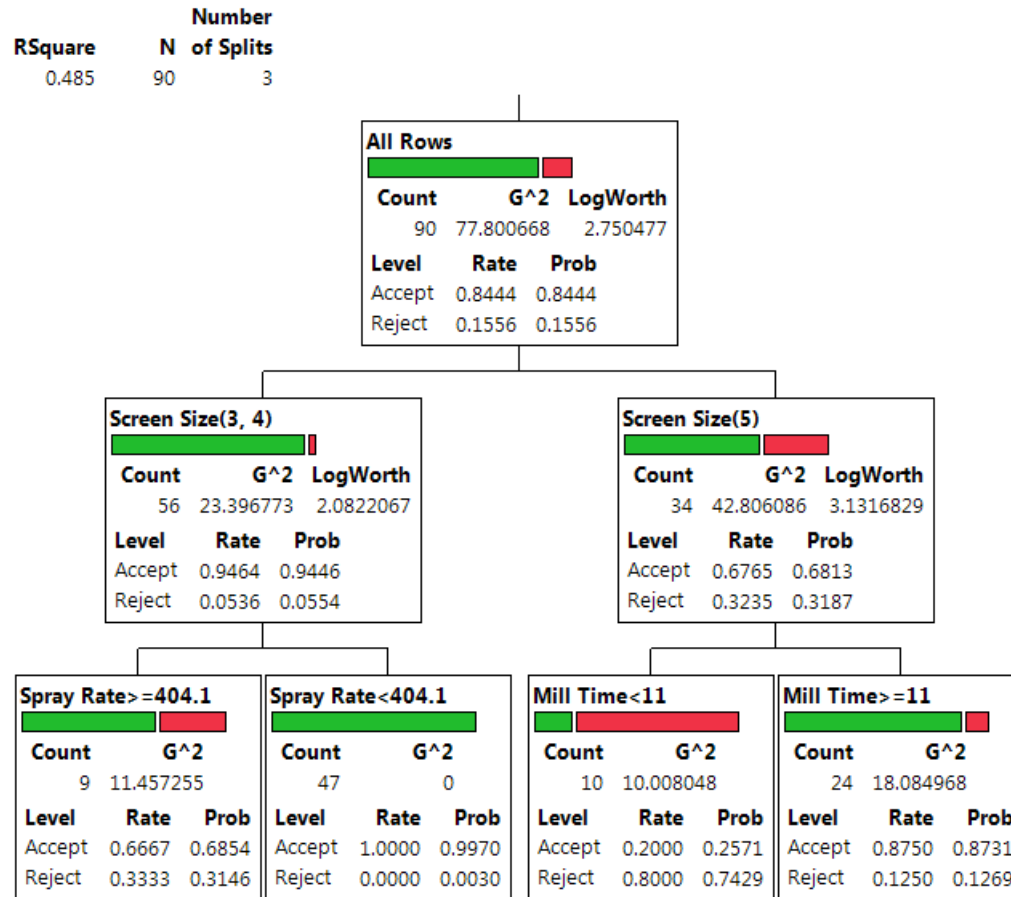

2nd split on Mill Time
(< 11 vs. >= 11)

Notice variation in
proportion of "1" in each
branch

Decision Tree (Step by Step)

3rd split on Spray Rate
(>= 404.1 vs. < 404.1))

Notice variation in
proportion of "1" in each
branch

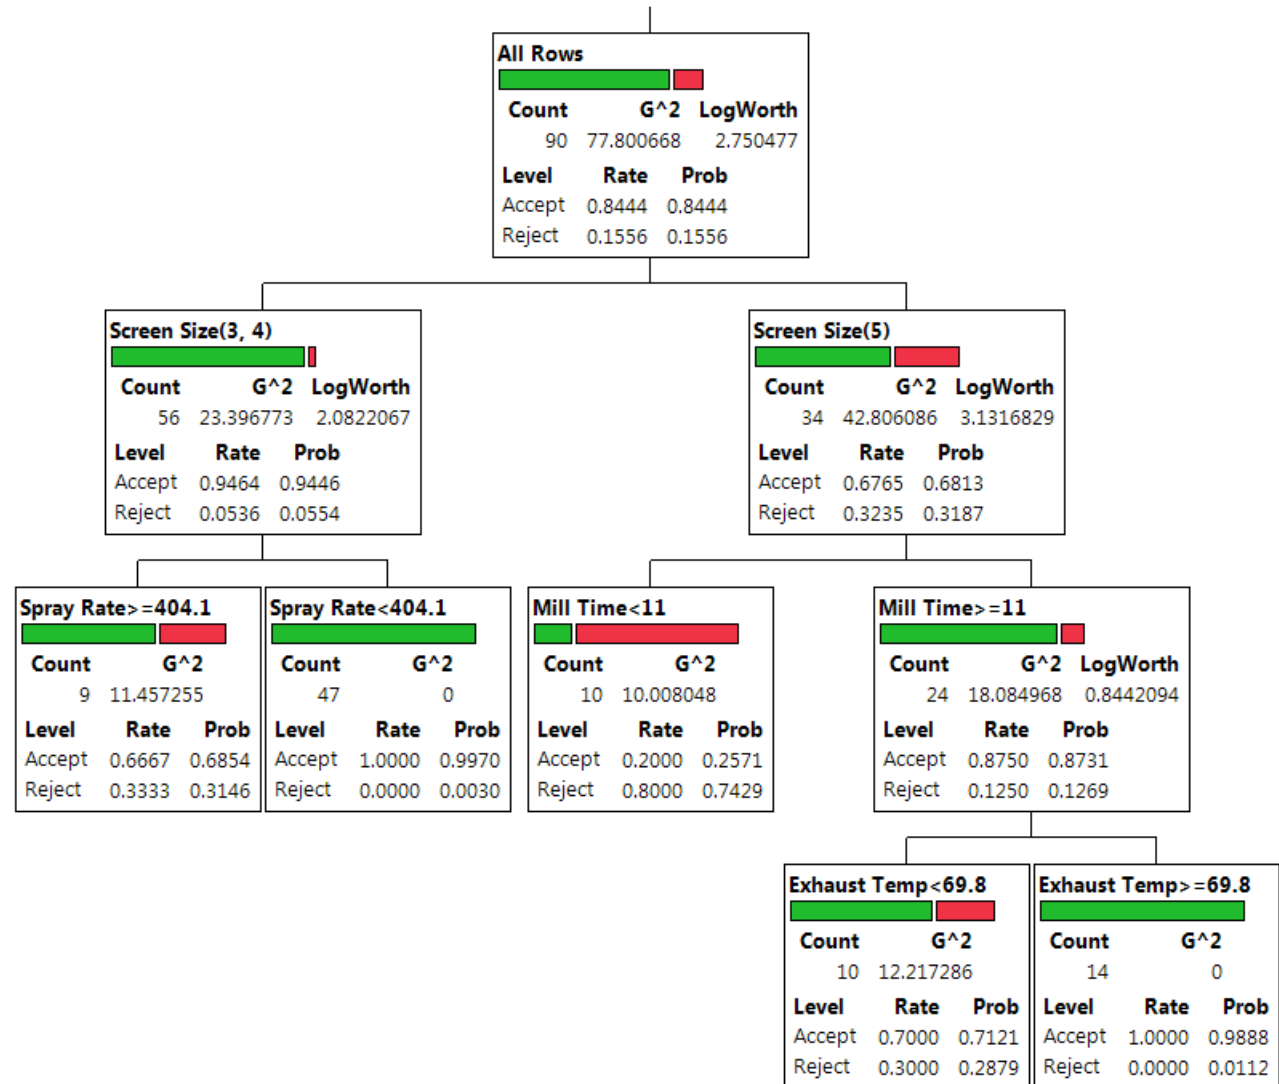

Decision Tree (Step by Step)

4th split on Exhaust Temp
(< 69.8 vs. ≥ 69.8)

Notice variation in
proportion of "1" in each
branch

RSquare 0.557
Number of Splits 90 4

Decision Tree (Step by Step)

RSquare 0.583
Number of Splits 90 5

5th split on Force
(< 25.0 vs. ≥ 25.0)

Notice variation in proportion of "1" in each branch

Decision Tree (Step by Step)

Bootstrap Forest

- Bootstrap Forest
 - For each tree, take a random sample of the predictor variables (**with replacement**) – e.g. pick half of the variables. Build out a decision tree on that subset of variables.
 - Make many trees and average their predictions (bagging)
 - This is also known as a random forest technique
 - Works very well on wide tables.
- Can be used for **both** predictive modeling and variable selection.
- Allows for dominant variables to be excluded from some trees giving less dominant – but still important – variables a chance to be selected.
- Valuable approach for screening variables for use with other modeling methods – e.g. neural networks.

Boosted Tree

- Beginning with the first tree (layer) build a small simple tree.
- From the residuals of the first tree, build another small simple tree.
- This continues until a specified number of layers has been fit, or a determination has been made that adding successive layers doesn't improve the fit of the model.
- The final model is the weighted accumulation of all of the model layers.

Boosted Tree Illustrated

Final Model

$$M = M1 + \varepsilon \cdot M2 + \varepsilon \cdot M3 + \dots + \varepsilon \cdot M49$$

ε is the learning rate

Neural Networks

- Neural Networks are highly flexible nonlinear models.
- A neural network can be viewed as a weighted sum of nonlinear functions applied to linear models.
 - The nonlinear functions are called activation functions. Each function is considered a (hidden) node.
 - The nonlinear functions are grouped in layers. There may be more than one layer.
- Consider a generic example where there is a response Y and two predictors $X1$ and $X2$. An example type of neural network that can be fit to this data is given in the diagram that follows

Example Neural Network Diagram

Neural Networks

- Big Picture
 - Can model:
 - » Continuous and categorical predictors
 - » Continuous and categorical responses
 - » Multiple responses (simultaneously)
 - Can be numerically challenging and time consuming to fit
 - NN models are very prone to overfitting if you are not careful
 - » There are several ways to help prevent overfitting
 - » Some type of validation is required

Choosing the Best Model

- In many situations you would try many different types of modeling methods
- Even within each modeling method, there are options to create different models
 - In Stepwise, the base/full model specification can be varied
 - In Bootstrap Forest, the number of trees and number of terms sample per split
 - In Boosted Tree, the learning rate, number of layers, and base tree size
 - In Neural, the specification of the model, as well as the use of boosting
- So how can you choose the “best”, most useful model?

The Importance of the Test Set

- One of the most important uses of having a training, validation, AND test set is that you can use the test set to assess each model on the same basis.
- Using the test set allows you to compare competing models on the basis of model quality metrics
 - R^2
 - Misclassification Rate
 - Actual vs. Prediction (Confusion Matrix)
 - ROC (Receiver Operating Characteristics) Curves and AUC (Area Under Curve – of ROC Curve)

Measures of Fit for PropIdentINS

Metrics for Just the Test Subset

| Predictor | Creator | .2.4.6.8 | RSquare | RASE | AAE | Freq |
|---|----------------|----------|---------|--------|--------|------|
| GLM ALL Data Pred Formula PropIdentINS | | | 0.8736 | 0.1397 | 0.0917 | 1292 |
| Partition K-Fold PropIdentINS Predictor | Partition | | 0.9172 | 0.1131 | 0.0595 | 1292 |
| BF - PropIdentINS Predictor | | | 0.9149 | 0.1147 | 0.0609 | 1292 |
| BT - PropIdentINS Predictor | | | 0.9130 | 0.1159 | 0.0619 | 1292 |
| NN Single Layer 33% Predicted PropIdentIN | Neural | | 0.9069 | 0.1199 | 0.0560 | 1292 |
| NN - Predicted PropIdentINS | | | 0.9105 | 0.1176 | 0.0570 | 1292 |
| Probability(PropIdentINS=1) | Fit Generalize | | 0.8719 | 0.1407 | 0.0925 | 1292 |

PropIdentINS & Mean(PropIdentINS) vs. GLM train set - Pred Formula PropIdentIN

PropIdentINS & Mean(PropIdentINS) vs. BF - PropIdentINS Predictor

PropIdentINS & Mean(PropIdentINS) vs. NN - Predicted PropIdentINS

Summary

- Learned about different data mining/model building methods
 - BUT, before building any models, use an “Honest Assessment” division of data into Train, Validate(Tune) and Test subsets to make models robust to overfitting AND comparisons of models fair
- Discussed creation of and showed results for some of these models fitting simulation data of helicopter surveillance
 - Decision Tree – Partition, Bootstrap Forest, Boosted Tree
 - Neural Net – Single Layer, Dual Layer, Boosted Neural
 - Generalized Linear Model (GLM) – Binomial Dist. w/Logit Link
- Evaluate and compare to choose best predictor
 - Table of metrics including R-Square
 - Plots of Actual vs. Predicted for the Test subset
- Gain insight into simulation model
 - Compare Prediction Profilers for different models – some are “smooth” models and some have “cut points”

THE
POWER
TO KNOW.
